# Migrating to GCP

---

- Many organizations want to migrate their apps to the cloud
- Various motivations
- Has to be planned ahead, and done methodically
- Rushing to the cloud could end up badly
- There's a well defined process that should be followed in order for the migration to complete successfully

# The Migration Process

# Motivation Assessment

---

- Answer the grand question:

**Why?**

(do we want to migrate to the  
cloud)

# Possible Answers

---

- To save costs
- To take advantage of cloud capabilities (services, redundancy, scalability, etc)
- To modernize the system
- To attract new employees

# Saving Costs

---

- Not always the case
- Sometimes cloud system can cost MORE than on-premises system
- CapEx vs OpEx
- A very thorough cost estimation should be conducted

# Take Advantage of Cloud Capabilities

---

- Great motivation! (probably the best...)
- Make sure the migrated system can actually use cloud capabilities
- Example: Legacy, single-session app that cannot be scaled will end up on a single VM, just like on-prem

# Modernize the System

---

- Usually, Modernization = Rewrite
- Why?
- Possible answers:
  - Not supported platforms
  - Difficult to hire employees
  - Licensing costs

# Attract New Employees

---

- Not a very good motivation, but it works...
- The organization has to be part of the cloud trend in order to attract new employees

# Migration Strategies

---

## Lift & Shift

Install the app in the cloud “as-is”, without any changes, usually on a VM

## Refactoring

Modify the app a bit so it can run on managed services (ie. App Engine, Cloud Run)

## Rewrite

Rewrite the app from scratch, usually in a modern platform, and take advantage of all cloud services

# Lift & Shift

On-Premise

**VM**  
**Java App**

**VM**  
**Oracle DB**

Cloud

# Refactor

## On-Premise

**VM**  
nodeJS App

**VM**  
MySQL DB

## Cloud

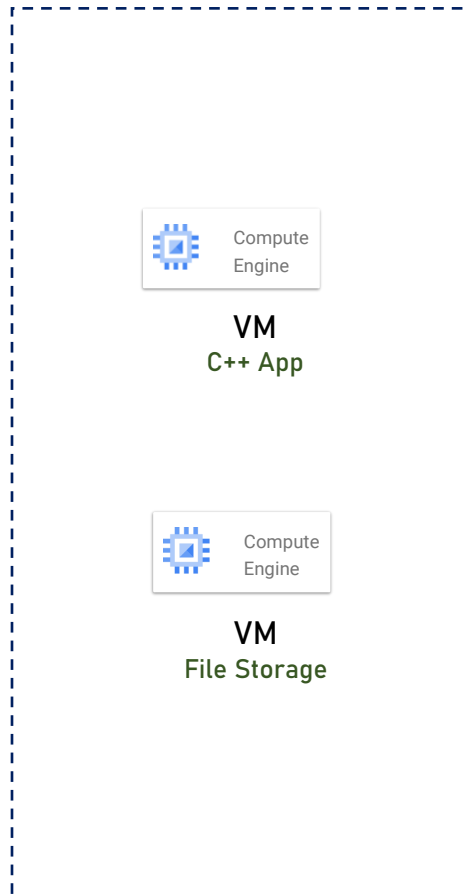

**App Engine**  
nodeJS App

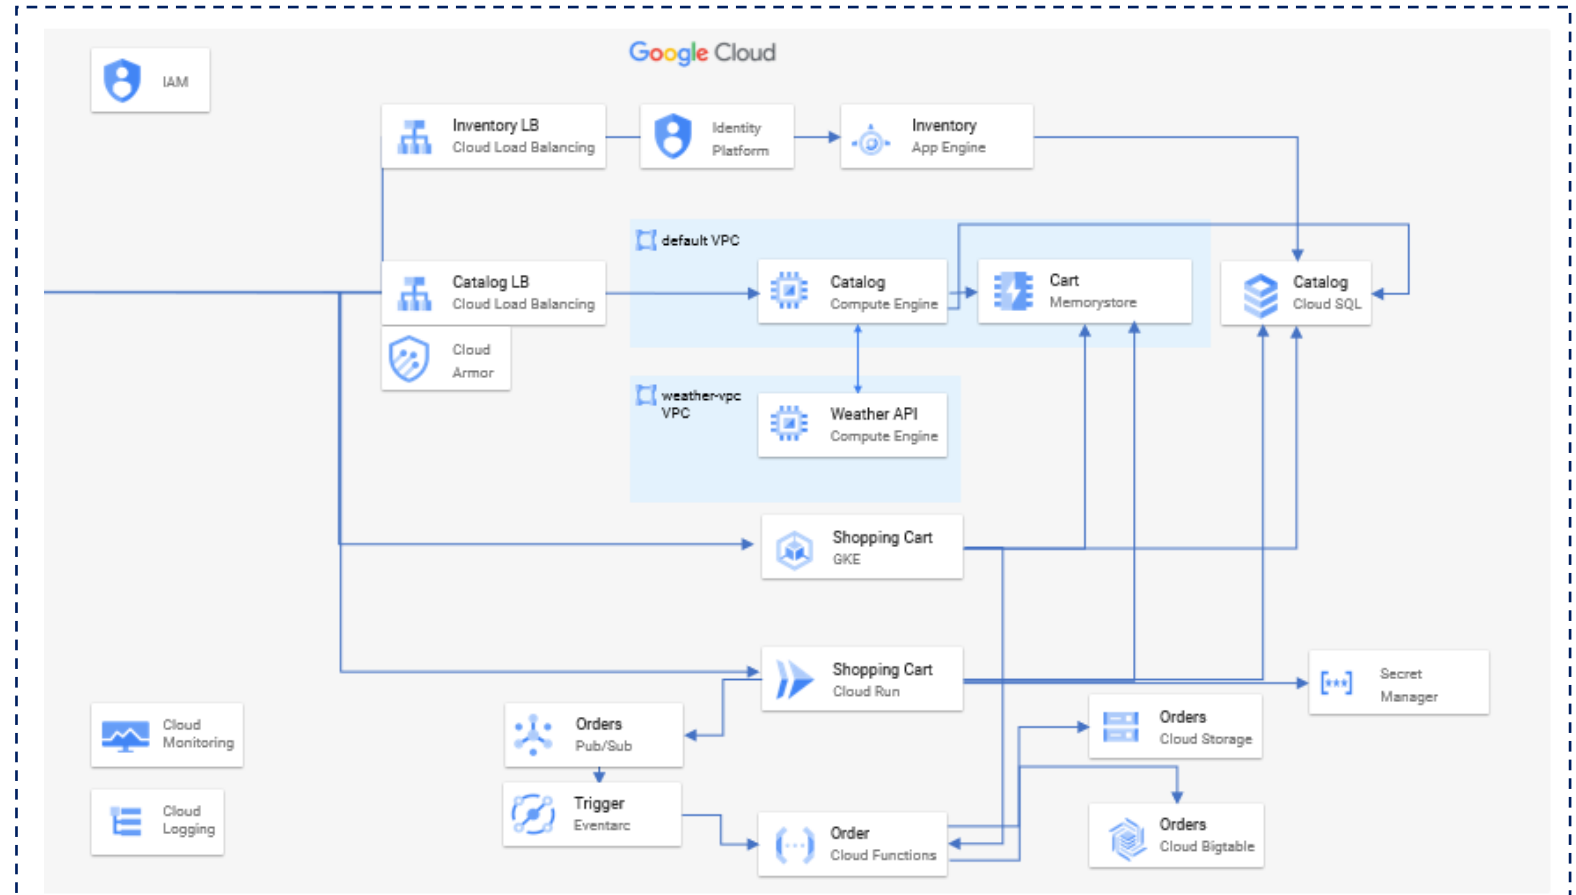

**Cloud SQL**

# Rewrite

## On-Premise

## Cloud

# Comparing Cloud Migration Strategies

# System Assessment

---

- Goal:
  - To find out what is the best way to migrate the system to the cloud
  - Doing this by asking the right questions

# System Assessment

- Questions we need to ask:

What is the runtime platform of the system and on which OS? (.NET, Java, C++ etc.)

How is it deployed today? (VM, Docker...)

What database(s) is used?

What is the authentication mechanism?

Any interfaces to organizational systems?

Any work with hardware? (dongles...)

# System Assessment

- Answers dictate migration strategy, if possible at all:

What is the runtime platform of the system and on which OS? (.NET, Java, C++ etc.)

What is the authentication mechanism?

How is it deployed today? (VM, Docker...)

Any interfaces to organizational systems?

What database(s) is used?

Any work with hardware? (dongles...)

# System Assessment

What is the authentication mechanism?

How is it deployed today? (VM, Docker...)

Any interfaces to organizational systems?

What database(s) is used?

Any work with hardware? (dongles...)

# Migration

---

- Time for actual migration...
- Migration strategy depends on the system assessment results

# Lift & Shift

---

- The easiest strategy
- Simply create VM images and build new VMs in the cloud
- Don't forget to put VMs in appropriate VPC and define Firewall

Rules

# Refactor

---

- Should be done in two phases:
  - Lift & Shift – Make sure the app works in the cloud as-is
  - Refactor – gradually improve the system and integrate cloud services
- Don't try shortcuts!

# Rewrite

---

- Not really a migration...
- Design the system from the ground up to be cloud native
- Use as many cloud services as possible

# DB Migration

---

- In general:
  - Prefer the managed version of the DB (and not on a VM)
  - Migration is better done using the DB's own tools and not via cloud migration services

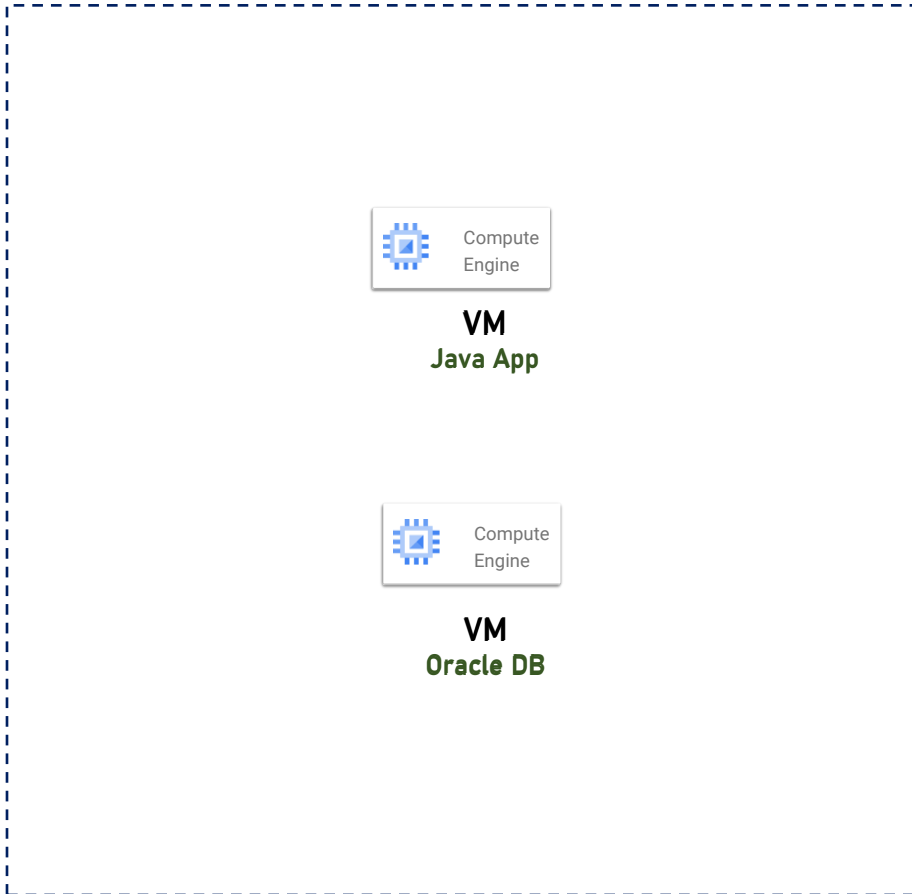

# App Enhancements

---

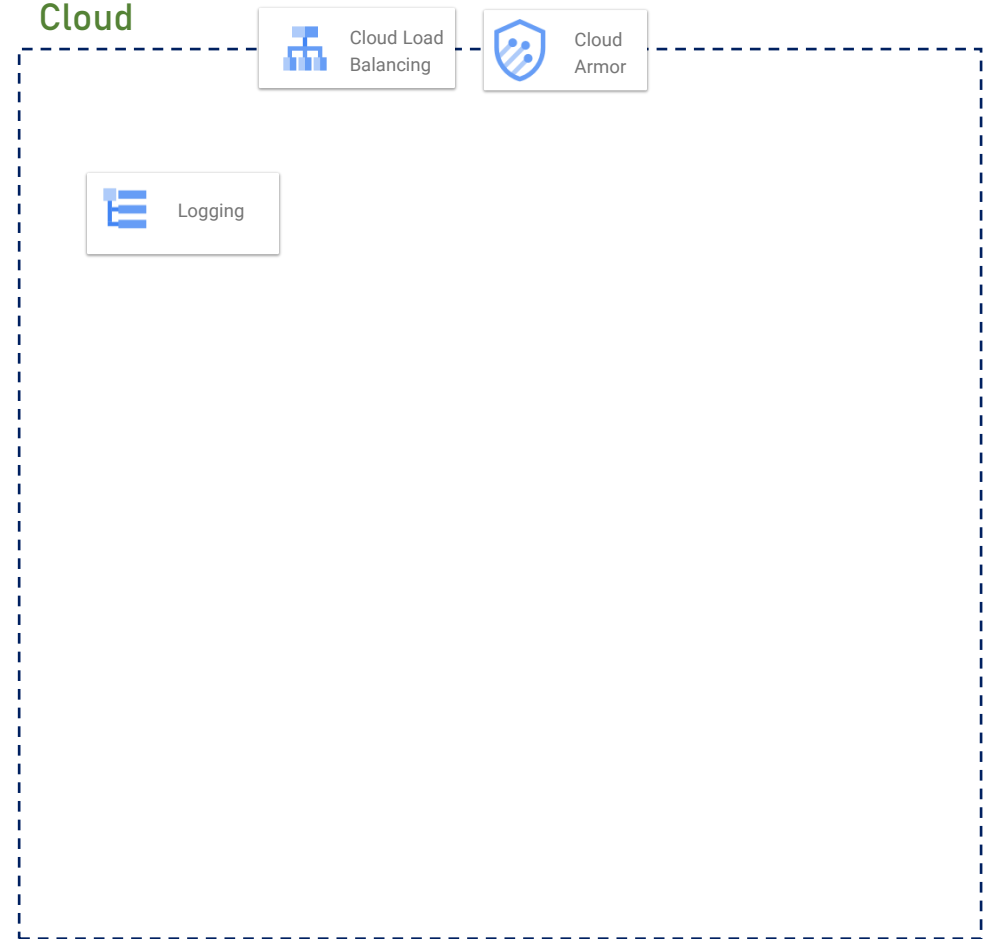

- After migration, enhance the system
- Not necessarily requires code changes
- Main areas for improvements:
  - Logging and Monitoring using Cloud Logging
  - Network protection using Load Balancer and Cloud Armor

# Lift & Shift Example

## On-Premise

## Cloud

# Testing

---

- Testing in cloud is similar to on-prem
- Put strong emphasis on logging and monitoring
- Make sure you have access to system's data
- If system is auto-scaled or DRed – test these scenarios
- Check performance – might vary from the on-prem figures

# Go Live

---

- Congratulations!
- Keep an eye on the costs
  - Set up budget alerts
  - Define tags
  - Look at the data at least once a month
